

RADIOCARBON AND TREE-RING DATES OF THE BES-SHATYR #3 SAKA KURGAN IN THE SEMIRECHIYE, KAZAKHSTAN

Irina Panyushkina¹ • Fedor Grigoriev² • Todd Lange³ • Nursan Alimbay⁴

ABSTRACT. This study employs tree-ring crossdating and radiocarbon measurements to determine the precise calendar age of the Bes-Shatyr Saka necropolis (43°47'N, 81°21'E) built for wealthy tribe leaders in the Ili River Valley (Semirechiye), southern Kazakhstan. We developed a 218-yr tree-ring chronology and a highly resolved sequence of ¹⁴C from timbers of Bes-Shatyr kurgan #3. A 4-decadal-point ¹⁴C wiggle dates the Bes-Shatyr necropolis to 600 cal BC. A 47-yr range of cutting dates adjusted the kurgan date to ~550 BC. This is the first result of high-resolution ¹⁴C dating produced for the Saka burials in the Semirechiye. The collective dating of Bes-Shatyr indicates the early appearance of the Saka necropolis in the Semirechiye eastern margins of the Saka dispersal. However, the date is a couple of centuries younger than previously suggested by single ¹⁴C dates. It is likely that the Shilbiyr sanctuary (location of the Bes-Shatyr) became a strategic and sacral place for the Saka leadership in the Semirechiye long before 550 BC. Another prominent feature of the Semirechiye burial landscape, the Issyk necropolis enclosing the Golden Warrior tomb, appeared a few centuries later according to ¹⁴C dating reported by other investigators. This study contributes to the Iron Age chronology of Inner Asia, demonstrating successful results of ¹⁴C calibration within the Hallstatt Plateau of the ¹⁴C calibration curve. It appears that the wide range of calibrated dates for the Saka occurrences in Kazakhstan (from 800 BC to AD 350) is the result of the calibration curve constraints around the middle of the 1st millennium BC.

INTRODUCTION

In the 1950s, K A Akishev discovered a grand necropolis of 31 kurgans in a tributary valley of the Ili River and called it Bes-Shatyr. The Iliyskaya Archaeological expedition surveyed and excavated archaeological occurrences in the Semirechiye region south of Lake Balkhash between the Tian-Shan and Altai Mountains (present-day Kazakhstan), and attributed the kurgans of Iron Age nomadic tribes to the Saka culture (Akishev and Kushayev 1963). The Semirechiye belongs to one of the most prominent sanctuaries of Saka wealthy tribes in Inner Asia. The original research on the kurgans established that a large volume of wood beams was used in the necropolis construction, which is typical for large burials of the Saka people, Indo-Europeans who inhabited Inner Asia in the 1st millennium BC (Iron Age) and spoke an Iranian language. However, to date the wood has yet to be used to develop a highly resolved radiocarbon series from the tree rings for precise dating of Saka occurrences in the Semirechiye.

Hall (1997) used calibrated ¹⁴C dates from the region to tentatively date the Saka kurgans of Semirechiye between the 6th and 4th centuries BC. Previously, regional material chronologies indicated a broader range of dates for the onset of Saka culture from as early as the 8th to the 2nd centuries BC (Yablonsky 1995). The agreement of recently calibrated ¹⁴C dates with other dates derived from art-historic and stylistic approaches in eastern Kazakhstan extended this dating range even further from 750 BC to AD 350. Recent success of the international “Gold of Nomads” exhibits (Chang and Guroff 2008) that included opulent golden artifacts from the exclusive Saka kurgans of the Issyk and Chilikta (or Shylikty) necropolises in eastern Kazakhstan, brought to light the problems in dating of the Saka kurgans once again.

The dating scheme of the Saka chronology in Kazakhstan has been under revision for the last decade (Kristiansen 2008). Nonetheless, the backbone of the Saka chronology remains the 3 necropolises: Issyk, Chilikta, and Bes-Shatyr. The Issyk kurgan (or Golden Warrior tomb) from the Talgar fluvial fan, the largest excavated kurgan in the Semirechiye, suggests the 3rd and 2nd centuries BC as a period of notable occurrence of wealthy Saka kurgans in the Semirechiye. Formerly, Akishev (1978) assigned the Issyk kurgan the 6th and 3rd centuries BC. Jacobson (1993) refers the Issyk kurgan to 4th and 3rd centuries BC and later to the 5th century BC (Chang and Guroff 2008). The latest published date was 2255 ± 39 ^{14}C yr with a 2σ calibrated interval between 400 and 200 BC (Zaitseva et al. 2005). The date was run on wood sampled from a leg of a small portable table. North of the Semirechiye, i.e. in the Jungarskiy Alatau, the Chilikta kurgans frame the earliest appearance of the Saka nomadic nobility between the 8th and 7th centuries BC based on ^{14}C dating (Hall 1997; Panyushkina, unpublished data). Yet, the age of the Chilikta site has been recently ascribed to the 8th century BC and the 5th–2nd centuries BC (Chernikov 1975; Hall 1997; Toleubaev 2010). As for the Bes-Shatyr necropolis, the burial objects (bronze arrowheads, in particular) date the site between the 6th and 3rd centuries BC (Akishev and Kushayev 1963). Later, the Bes-Shatyr age was narrowed to the interval of 5th to 3rd centuries BC through revision of the material chronologies (Akishev 1978). In contrast, calibrated ^{14}C dates expanded its range to between 800–750 BC (Zaitseva et al. 2005) and AD 40–420 (Hall 1997).

It was previously thought that the older kurgans of the nomadic wealthy in eastern Kazakhstan occurred in the Altai and Djungarskiy Alatau Mountains and the younger ones in the Semirechiye, southward near the Tian Shan Mountains (Chang et al. 2003). Calibration results of recent ^{14}C dates obliterated the difference in ages of these 2 regions due to the wide 2σ calibrated intervals caused by constraints of the ^{14}C calibration curve around the middle of the 1st millennia BC (the Hallstatt Plateau). Thus, the few recent ^{14}C dates posed more questions than answers for the Saka chronology at the eastern margins of the Eurasian Steppe. This study analyzes a sequence of ^{14}C dates from tree rings of the Bes-Shatyr kurgan #3 with an emphasis on precisely estimating absolute age of the kurgan by a best match to the IntCal09 calibration curve and suggests an absolute calendar date of the Bes-Shatyr necropolis.

MATERIAL AND METHODS

Bes-Shatyr kurgan #3 ($43^{\circ}47'\text{N}$, $81^{\circ}21'\text{E}$) is a part of the Bes-Shatyr necropolis located on the east bank of the Ili River just outside of Shilbiyr Gorge, Ile-Alatauskiy National Park. The Bes-Shatyr necropolis is a group of 31 kurgans stretching along a 2-km semidesert terrain and organized in southern and northern rows ~500 m apart. The northern row incorporates 4 large kurgans including the studied kurgan #3, which is the second largest kurgan in the group, sited next to the largest kurgan of the necropolis (the Great kurgan: 104 m base diameter and 15 m height). The base diameter of kurgan #3 is 75 m, its height is 11.5 m (equal to a 3-story building). The complex structure of kurgan #3 was built from 17 stone-earthen layers walled with stones. It had a wooden tomb erected above the ground with a grid of underground passages. The tomb has been burned down sometime before construction of the burial mound. The tomb looked like a well-built large long house. All beams used in the tomb construction had been wood-worked. The studied specimens had partially burned or removed sapwood, but the outermost rings representing the cutting dates survived in the beams along some parts of the tree circumference. Massive beams had a pair of round cut-through handles near the ends to tie a rope for ease of transport. Unfortunately, as is frequently the case, most of the tomb timbers were lost after excavation or were reburied on the site.

¹⁴C and Tree-Ring Dates of the Bes-Shatyr #3

Five cross-sections were collected from the tomb remnants during clean-up of the kurgan by the KAZ-Restoration development project in 2011–2012. The tree rings were crossdated using tree-ring width series measured and overlapped with TSAP software (Rinn 2003). Four consecutive subsamples of 10-yr ring groups were cut from burned specimen #1 (Figure 1). The tree-ring subsamples were ground to 20-mesh and initially converted to holocellulose by the Jayme-Wise method modified after Leavitt and Danzer (1993). At the Laboratory of Tree-Ring Research (University of Arizona), the powdered wood was first extracted with toluene/ethanol and then with ethanol organic solvents in a Soxhlet extraction apparatus, followed by boiling in deionized water. Samples were delignified in an acetic acid-acidified, sodium chlorite aqueous solution at 70 °C, and then thoroughly rinsed in deionized water. Combustion to CO₂, graphite conversion, and ¹⁴C measurements using accelerator mass spectrometry were completed at the Arizona NSF Accelerator facility. The ¹⁴C dates were calibrated with CALIB 6.0 software (<http://calib.qub.ac.uk/calib/>) and the IntCal09 data set (Reimer et al. 2009).

Figure 1 Photo of wood specimen #1 subsampled for ¹⁴C dating. The charred end is the result of a fire that occurred in the Bes-Shatyr #3 tomb around the time of construction.

RESULTS AND DISCUSSION

Five collected specimens were identified as spruce (*Picea smithiana*), presently growing about 200–250 km away (the Zailiyskiy Alatau Range) from the semidesert archaeological site. The relatively large number of tree rings per specimen (179–211 rings), very slow rate of radial growth, and high cross-correlation of the 5 studied specimens ($r = 0.56$; $p > 0.01$) suggest that the mature trees came from the same location and grew under severe stress of external growth-limiting factors. Five cross-dated tree-ring width series overlapped into a 218-yr floating chronology (Figure 2) with the following range of the wood cutting dates: years 184, 210, 211, 216, and 217. The difference between the most recent cutting date (specimen #3) of the tree-ring chronology and the outermost ring of specimen #1 from which the ¹⁴C date was obtained is 33 yr. An extra 13 rings were added between the ¹⁴C-dated ring of sample #1 and the outside date of the specimen (rings 157–166 of the master tree-ring chronology). Consequently, a total of 47 rings are applied to correct the calendar age of kurgan resulting from calibration of the Bes-Shatyr-3 ¹⁴C wiggle.

Figure 2 Crossdated tree-ring width series and their mean (thick line) measured from 5 tree-ring specimens of the Bes-Shatyr kurgan #3 timbers. The span of cut dates is 33 yr. The ^{14}C dates were run on the interval from ring #127 to ring #166 of the chronology.

Four ^{14}C dates measured on a 40-calendar-year interval of the Bes-Shatyr kurgan #3 tree-ring series (Table 1) fell into a 63-yr interval between 2527 and 2464 ^{14}C BP, indicating low variability of the ^{14}C curve in the period of interest. The error of ^{14}C age estimation varies from 37 to 43 yr, which is comparable to other existing ^{14}C measurements for the Bes-Shatyr necropolis. The average ^{14}C age of the 4 outer decades is 2490 ^{14}C yr BP. This date is younger than 3 single ^{14}C dates run on wood from kurgans #1, #3, and kurgan #6 of the Bes-Shatyr necropolis previously reported by other studies (Dolukhanov et al. 1970; Zaitseva et al. 2005). Nevertheless, the ordering of the ^{14}C dates should be considered with caution for interpretations of the necropolis chronology because the other ^{14}C dates are problematic. The oldest ^{14}C measurement on a fragment of a wooden craft object from kurgan #6 published by Zaitseva et al. (2005) was 2570 ± 35 ^{14}C BP (LE-5643). The date calibrates between 820 and 750 cal BC (2σ). This old date does not represent the chronology of this kurgan well due to the obvious old-wood effect, but places a possible uppermost margin of the necropolis construction. Two other ^{14}C dates on wood submitted by Akishev and published by Dolukhanov et al. (1970) were 2550 ± 65 ^{14}C BP from kurgan #1 (LE-603) and 1850 ± 70 ^{14}C BP from kurgan #3 (LE-590). The calibrated interval is 820–490 cal BC (2σ) for kurgan #1 and 340 cal BC–cal AD 5 (2σ) for kurgan #3. The type of wood is unknown in both cases. The kurgan #1 date (Dolukhanov et al. 1970) is similar in age to kurgan #6 (Zaitseva et al. 2005), but the kurgan #3 date (Dolukhanov et al. 1970) is too young for the studied kurgan group (~ 700 ^{14}C yr younger) and not reliable for the dating. The updated and revised IntCal09 calibration data set used in CALIB 6.0 suggests little difference in the calibrated intervals used here and by Hall (1997). It is conceivable that kurgan #1 and kurgan #6 predate kurgan #3.

The 4-point ^{14}C wiggle sequence of the Bes-Shatyr kurgan #3 fits well to the shape of the linear calibration curve ending at ~ 600 cal BC (Figure 3). All 4 measurements clearly emerge before the first peak of the ^{14}C Hallstatt Plateau. Adding the 47 yr omitted from the ^{14}C dating to the calibrated ^{14}C date suggests ~ 550 BC as the occurrence date of kurgan #3 at the Bes-Shatyr necropolis. Originally, the age and cultural identity of the Bes-Shatyr necropolis was determined using burial complexes of small kurgans of the cemetery because the large excavated kurgans of the site (#1, 2, 3, 6, 8, and the Great kurgan) were completely robbed in ancient times and the tomb of kurgan #3 was burned down before it had been covered with the earthen mound. Customarily, the smaller kurgans are added later to a noble cemetery. Kurgan # 25 (base diameter 8.5 m and 1 m high) provided material objects (e.g.

¹⁴C and Tree-Ring Dates of the Bes-Shatyr #3

wooden parts of armory, belt buckles, and bronze arrowheads) that date the cemetery to the 5th–3rd centuries BC (Akishev and Kushayev 1963). It is worth noting that the upper range of the stylistic dating corresponds well to the result from the highly resolved ¹⁴C dating.

Table 1 ¹⁴C ages of decadal ring groups from wood specimen #1 used in wiggle-matching (Bronk Ramsey et al. 2001) (Figure 3). Holocellulose pretreatment was done in the LTRR chemical Lab. Note: Column 3 gives the ring count of the tree-ring specimen, not the master tree-ring chronology. The ¹⁴C sequence contains consistent measurements with no suspected outliers.

Sample ID	Lab ID	Ring #	δ ¹³ C	Fm	¹⁴ C yr BP
Bes-5	AA #97421	121–130	–20.2	0.7357 ± 0.0034	2465 ± 37
Bes-4	AA #97420	131–140	–20.0	0.7321 ± 0.0039	2504 ± 43
Bes-3	AA #97419	141–150	–20.4	0.7301 ± 0.0035	2527 ± 38
Bes-2	AA #97418	151–160	–20.5	0.7358 ± 0.0036	2464 ± 39

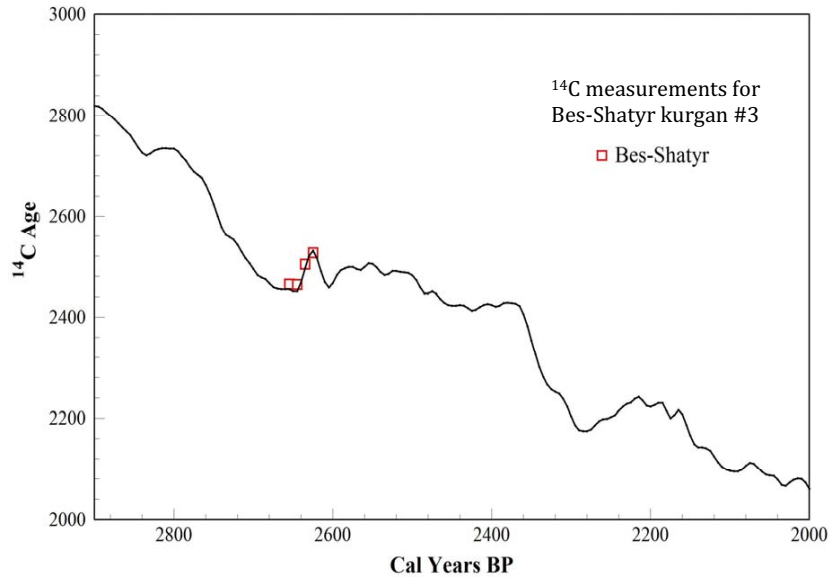

Figure 3 High-resolution ¹⁴C calibration of the tree-ring sequence for Bes-Shatyr kurgan #3. The plot shows the best visual fits of ¹⁴C dates with the IntCal09 calibration curve (Reimer et al. 2009).

Calibration of single ¹⁴C dates from the Bes-Shatyr necropolis produces ambiguous results. It has not yet been feasible to achieve precise dating of Saka occurrences with a single ¹⁴C measurement. The challenging features of the calibration curve shape during the middle of the 1st millennium BC produce large offsets in calibrated calendar ages. Figure 4 demonstrates the enormous multicentury calibration intervals (1 and 2σ) for a ¹⁴C single measurement of a 10-yr tree-ring group used for the development of the highly resolved ¹⁴C series for kurgan #3 (see last 2 dates in Table 1). In this case, the accuracy of calibrated dates does not depend on the precision of ¹⁴C measurements either. A measurement with a 39-yr error may fall into the same calibrated interval as a measurement with a 75-yr error (see calibration results of kurgan #1 above). It appears that multiple ¹⁴C measurements of the same sample with a known chronological order of subsamples (e.g. like tree rings) increase the accuracy of dating of the Saka kurgans. Another way to determine the order and precise age of other large

kurgans from the Bes-Shatyr necropolis is dendrochronological dating. Analysis of small pieces of wood (<50 rings) collected at kurgan #6 indicates that wood of spruce with highly sensitive tree rings was used in construction of this kurgan as well. Any spruce wood from Saka kurgans of the Semirechiye, which most likely date to the middle of the 1st century BC, could potentially be suitable for crossdating. The developed master tree-ring chronology of kurgan #3 spans from 730 to 550 BC as determined with the highly resolved ^{14}C series of that kurgan.

Figure 4 Two examples of calibration results of a single ^{14}C date measured on outer tree rings of the studied kurgan #3 wood specimen (Table 1). The displayed wide range of calendar intervals is caused by the Hallstatt Plateau, a relatively flat period in the calibration curve between 800 and 400 BC.

In conclusion, we believe that the collective dating of the Bes-Shatyr suggests that the Bes-Shatyr wealthy kurgans were erected from 750 to 550 BC. It is possible that kurgan #3, dated to 550 BC, is the latest kurgan constructed at the Bes-Shatyr necropolis. Bes-Shatyr appears to be the oldest wealthy burial site in the Semirechiye as determined by precise ^{14}C dating. The site is 200–250 yr younger than it was determined with single ^{14}C dates previously. This eliminates the huge gap between erection of the Issyk and Bes-Shatyr burial grounds—the 2 most prominent excavated sites of Saka culture in the Semirechiye. The Bes-Shatyr kurgan #3 (Semirechiye West) preceded the elite burials of Saka from the Issyk (Semirechiye East) by about 150 yr.

Tree rings from the wooden burial structures of Saka are a tremendous asset for refining the dynamic history of nomadic tribes during the 1st millennium BC. Additional highly resolved ^{14}C records from tree rings are in great demand for reconstructing the spatial/temporal patterns of Saka culture in the Semirechiye and Inner Asia. Furthermore, there can be no comprehensive understanding of Saka interactions with ancient people of the neighboring regions of modern Mongolia, Siberia, China (e.g. Xinjiang and Tarim Basin), Afghanistan, and Uzbekistan unless the ^{14}C dates can be resolved within the Hallstatt Plateau of the ^{14}C calibration curve.
